Brain damage and cerebral edema: a 3D quantitative diffusion tensor imaging study of cerebral contusions in a rat model. The purpose of this study was to assess brain damage after traumatic brain injury (TBI) by quantitative diffusion tensor imaging (qDTI). Diffusion tensor images were acquired from the rat corpus callosum on day 1 and

day 3 after fluid percussion injury (FPI). Mean diffusivity (MD) was determined from diffusion tensor images. The contusions were assessed on day 1 and day 3 after TBI by means of magnetization transfer imaging, immunohistochemistry and fluorescent microscopy. Fractional anisotropy (FA) was also calculated and the results were compared to MD. After FPI, MD increased significantly on day 1 compared to the contralateral side in the lesion core and rim. FA

decreased significantly on day 1 in the lesion core but increased in the lesion rim on day 3 compared to the contralateral side.

Immunohistochemical staining showed a mild loss of neurons in the core and rim of the lesion on day 3 after FPI. These findings indicate that MD increases in the lesion core and rim, whereas FA decreases in the lesion core and increases in the lesion rim.Q:
